#### Field of the Invention

The present invention relates generally to a series of novel small molecules, their synthesis and their use in the treatment of inflammatory disease.

#### 10 Background of the Invention

Research spanning the last decade has helped to elucidate the molecular events attending cell-cell interactions in the body, especially those events involved in the movement and activation of cells in the immune system. See generally, Springer, T. Nature, 1990, 346, 425-434. Cell surface proteins, and especially the Cellular Adhesion Molecules ("CAMs") and "Leukointegrins", including LFA-1, MAC-1 and gp150.95 (referred to in WHO nomenclature as CD18/CD11a, CD18/CD11b, and CD18/CD11c, respectively) have correspondingly been the subject of pharmaceutical research and development having as its goal the intervention in the processes of leukocyte extravasation to sites of injury and leukocyte movement to distinct targets. For example, it is presently believed that prior to the leukocyte extravasation, which is a mandatory component of the inflammatory response, activation of integrins constitutively expressed on leukocytes occurs and is followed by a tight ligand/receptor interaction between integrins (e.g., LFA-1) and one or several distinct intercellular adhesion molecules (ICAMs) designated ICAM-1, ICAM-2, ICAM-3 or ICAM-4 which are expressed on blood vessel endothelial cell surfaces and on other leukocytes. The interaction of the CAMs with the Leukointegrins is a vital step in the normal functioning of the immune system. Immune processes such as antigen presentation, T-cell mediated cytotoxicity and leukocyte extravasation all require cellular adhesion mediated by ICAMs interacting with the Leukointegrins. See generally Kishimoto, T. K.; Rothlein; R. R. Adv. Pharmacol. 1994, 25, 117-138 and Diamond, M.; Springer, T. Current Biology, 1994, 4, 506-532.

A group of individuals has been identified which lack the appropriate expression of Leukointegrins, a condition termed "Leukocyte Adhesion Deficiency" (Anderson, D. C.; et al., Fed. Proc. 1985, 44, 2671-2677 and Anderson, D. C.; et al., J. Infect. Dis. 1985, 152, 668-689). These individuals are unable to mount a normal inflammatory and/or immune response(s) due to an inability of their cells to adhere to cellular substrates. These data show that immune reactions are mitigated when lymphocytes are unable to adhere in a normal fashion due to the lack of functional adhesion molecules of the CD18 family. By virtue of the fact that LAD patients who lack CD18 cannot mount an inflammatory response, it is believed that antagonism of CD18, CD11/ICAM interactions will also inhibit an inflammatory response.

10

15

20

25

30

It has been demonstrated that the antagonism of the interaction between the CAMs and the Leukointegrins can be realized by agents directed against either component. Specifically, blocking of the CAMs, such as for example ICAM-1, or the Leukointegrins, such as for example LFA-1, by antibodies directed against either or both of these molecules effectively inhibits inflammatory responses. In vitro models of inflammation and immune response inhibited by antibodies to CAMs or Leukointegrins include antigen or mitogeninduced lymphocyte proliferation, homotypic aggregation of lymphocytes, T-cell mediated cytolysis and antigen-specific induced tolerance. The relevance of the in vitro studies are supported by in vivo studies with antibodies directed against ICAM-1 or LFA-1. For example, antibodies directed against LFA-1 can prevent thyroid graft rejection and prolong heart allograft survival in mice (Gorski, A.; Immunology Today, 1994, 15, 251-255). Of greater significance, antibodies directed against ICAM-1 have shown efficacy in vivo as anti-inflammatory agents in human diseases such as renal allograft rejection and rheumatoid arthritis (Rothlein, R. R.; Scharschmidt, L., in: Adhesion Molecules; Wegner, C. D., Ed.; 1994, 1-38, Cosimi, C. B.; et al., J. Immunol. 1990, 144, 4604-4612 and Kavanaugh, A.; et al., Arthritis Rheum. 1994, 37, 992-1004) and antibodies directed against LFA-1 have demonstrated immunosuppressive effects in bone marrow transplantation and in the prevention of early rejection of renal allografts (Fischer, A.; et al., Lancet, 1989, 2, 1058-1060 and Le Mauff, B.; et al., Transplantation, 1991, 52, 291-295).

It has also been demonstrated that a recombinant soluble form of ICAM-1 can act as an inhibitor of the ICAM-1 interaction with LFA-1. Soluble ICAM-1 acts as a direct antagonist of CD18,CD11/ICAM-1 interactions on cells and shows inhibitory activity in *in vitro* models of immune response such as the human mixed lymphocyte response, cytotoxic T cell responses and T cell proliferation from diabetic patients in response to islet cells (Becker, J. C.; *et al.*, *J. Immunol.* 1993, 151, 7224 and Roep, B. O.; *et al.*, *Lancet*, 1994, 343, 1590).

Thus, the prior art has demonstrated that large protein molecules which antagonize the binding of the CAMs to the Leukointegrins have therapeutic potential in mitigating inflammatory and immunological responses often associated with the pathogenesis of many autoimmune or inflammatory diseases. However proteins have significant deficiencies as therapeutic agents, including the inability to be delivered orally and potential immunoreactivity which limits the utility of theses molecules for chronic administration. Furthermore, protein-based therapeutics are generally expensive to produce.

of CAMs and Leukointegrins. A natural product isolated from the root of *Trichilia rubra* was found to be inhibitory in an *in vitro* cell binding assay (Musza, L. L.; et al., Tetrahedron, 1994, 50, 11369-11378). One series of molecules (Boschelli, D. H.; et al., J. Med. Chem. 1994, 37, 717 and Boschelli, D. H.; et al., J. Med. Chem. 1995, 38, 4597-4614) was found to be orally active in a reverse passive Arthus reaction, an induced model of inflammation that is characterized by neutrophil accumulation (Chang, Y. H.; et al., Eur. J. Pharmacol. 1992, 69, 155-164). Another series of molecules was also found to be orally active in a delayed type hypersensitivity reaction in rats (Sanfilippo, P. J.; et al., J. Med. Chem. 1995, 38, 1057-1059). All of these molecules appear to act nonspecifically, either by inhibiting the transcription of ICAM-1 along with other proteins or act intracellularly to inhibit the activation of the Leukointegrins by an unknown mechanism. None of the molecules directly antagonize the interaction of the CAMs with the

Leukointegrins. Due to lack of potency, lack of selectivity and lack of a specific mechanism of action, the described small molecules are not likely to be satisfactory for therapeutic use.

It follows that small molecules having the similar ability as large protein molecules to directly and selectively antagonize the binding of the CAMs to the Leukointegrins would make preferable therapeutic agents. WO9839303 discloses a class of small molecule inhibitors of the interaction of LFA-1 and ICAM-1. WO9911258 discloses that the fungal metabolite mevinolin and derivatives bind to LFA-1 and disrupt the interaction of LFA-1 and ICAM-1. WO9949856 discloses a class of peptidomimetic inhibitors of ICAM binding to LFA-1 and Mac-1.

#### Summary of the Invention

- A first aspect of the invention comprises a method for treating or preventing inflammatory and immune cell-mediated diseases by the administration of certain novel small molecules. These compounds act by inhibiting the interaction of cellular adhesion molecules, specifically by antagonizing the binding of human intercellular adhesion molecules (including ICAM-1, ICAM-2 and ICAM-3) to the Leukointegrins (especially
- 20 CD18/CD11a). A second aspect of the invention comprises novel small molecules having the above-noted therapeutic activities. A third aspect of the invention comprises methods for making these novel compounds. A final aspect of the invention comprises pharmaceutical compositions comprising the above-mentioned compounds suitable for the prevention or treatment of inflammatory and immune cell-mediated conditions.

As the term is used herein, a "pharmaceutically acceptable counter ion" is any counter ion generally regarded by those skilled in the pharmaceutical art as being pharmaceutically acceptable. For a discussion of what are pharmaceutically acceptable counter ions, reference may be had to Stephen M. Bergle, Lyle D. Bighley and Donald C. Monkhouse, "Pharmaceutical Salts", *Journal of Pharmaceutical Sciences*, 66 (1977), 1-19. By way of non-limiting example, the chloride, bromide, acetate, and sulphate ions are pharmaceutically acceptable counter ions.

## Synthesis of the Compounds of the Invention

Compounds of the invention may be prepared by the general methods described below. Typically, reaction progress may be monitored by thin layer chromatography (TLC) if

desired. If desired, intermediates and products may be purified by chromatography on silica gel and/or recrystallization, and characterized by one or more of the following techniques: NMR, mass spectroscopy and melting point. Starting materials and reagents are either commercially available or may be prepared by one skilled in the art using methods described in the chemical literature.

Intermediates used in the preparation of the compounds of formula I may be prepared by the method described below and outlined in Scheme I.

Scheme I

An appropriate amino acid (III) is dissolved in aqueous base (such as, for example, NaOH, KOH, Na<sub>2</sub>CO<sub>3</sub>, NaHCO<sub>3</sub>, K<sub>2</sub>CO<sub>3</sub> or KHCO<sub>3</sub>) and warmed to between about 20 and 90 °C. An appropriate isocyanate (IV) is added to this mixture and the resulting solution is stirred until the reaction essentially reaches completion. Upon cooling, the mixture is acidified and the resulting ureidoacetic acid is isolated by filtration or by extraction into

organic solvent. Removal of solvent produces the intermediate ureidoacetic acid. In the manner reported by Sauli (US Patent 4,099,008), the intermediate ureidoacetic acid is cyclized by heating in the presence of a catalytic amount of acid (such as, for example, sulfuric acid, methanesulfonic acid, benzenesulfonic acid or hydrochloric acid) in an organic or aqueous solvent, to produce the desired hydantoin (V). Workup consists of collection of the hydantoin by filtration and purification by, for example, silica gel chromatography or recrystallization.

If the thiocarbonyl VII is desired, several reagents are known in the literature which will convert carbonyls to thiocarbonyls. A typical sequence involves heating the substrate with a reagent such as P<sub>2</sub>S<sub>3</sub> in a high boiling solvent such as tetralin for between 1 and 48 h. Isolation of the product follows relatively standard conditions such as the dilution of the mixture into an organic solvent such as EtOAc and washing this mixture with water and saturated aqueous NaCl followed by drying and concentration. Purification is accomplished by silica gel chromatography or recrystallization, to afford VI.

Intermediate VI can be selectively hydrolyzed to the desired monothiocarbonyl compound depending on the choice of conditions. In general the thiocarbonyl at the 4-position of the ring is more susceptible to nucleophilic conditions. It can be converted to the 4-oxospecies (VII) by treatment with aqueous ethanolamine followed by acid hydrolysis. Purification is easily performed by silica gel chromatography or recrystallization.

Alternatively, the methyl or ethyl ester of III may be reacted with an aryl thioisocyanate (IV: -NCS instead of -NCO) in a suitable solvent, such as 1,4-dioxane, under an inert atmosphere at about 50-100 °C for about 1-24 h to provide VII.

If one uses the racemic III or ester of III, the product (V or VII) is racemic at the asymmetric carbon. By starting with a single enantiomer of III or ester of III, one obtains the single enantiomer of V or VII.

Azide VIII is added to a solution of PPh<sub>3</sub> in a suitable solvent such as toluene, under inert atmosphere and allowed to stir at ambient temperature for about 12-24 h. The appropriate thiohydantoin VII is then added and the reaction heated under inert atmosphere, preferably in a sealed tube at about 130-140 °C for about 1-4 days to provide IX after concentration and purification by silica gel chromatography. An acid, such as trifluoroacetic acid, is added to a solution of IX in a solvent such as dichloroethane and heated under inert atmosphere at about 50-100 °C for about 12-24 h to provide I (A<sup>1</sup> = N, A<sup>2</sup> = CH, D = CH) after standard workup and purification.

Analogs of I ( $A^1 = N$ ,  $A^2 = CH$ ) where D is a carbon substituted with various groups, such as halogen, CN, CHO, an alkyl group, an alkyl or aryl sulfide, sulfoxide or sulfone, may be prepared as described below and outlined in Scheme III.

In Scheme III, M is a metal atom such as Li or Mg, Hal is Cl, Br or I and E is a functional group transferable by an electrophilic reagent and can be, but is not restricted to, Cl, Br, I, CN, alkyl, CHO, SO<sub>2</sub>M, SO<sub>2</sub>R or CO<sub>2</sub>R, where R is alkyl or aryl.

- The desired N-halosuccinimide (about 1 mole equivalent) is added in portions to a solution of I (A<sup>1</sup> = N, A<sup>2</sup> = CH, D = CH), in a suitable solvent such as methylene chloride at about -10 °C to ambient temperature, preferably at about 0 °C, and stirred for about 2 to 15 h. Following workup and purification, I (A<sup>1</sup> = N, A<sup>2</sup> = CH, D = C-Cl, C-Br, C-I) is obtained.
- The halogen substituted compound I ( $A^1 = N$ ,  $A^2 = CH$ , D = C-Cl, C-Br, C-I) may be transformed to an organometallic intermediate I ( $A^1 = N$ ,  $A^2 = CH$ , D = C-M, where M is a metal atom, such as Li or Mg) by treatment with an organometallic reagent, such as an

alkyl or aryl lithium or a Grignard reagent. This organometallic intermediate may be reacted with an electrophile, such as an N-chloro-, bromo- or iodo- succinimide, tosyl cyanide, an alkyl or aryl sulfonyl chloride, an alkyl or aryl disulfide, an alkyl- or arylthiosulfonate, an alkyl or aryl chloroformate, an alkyl halide, N,N-dimethylformamide or sulfur dioxide, to produce the anolog of I ( $A^1 = N$ ,  $A^2 = CH$ ) where D is a carbon substituted with various groups, such as Cl, Br, I, CN, an alkyl group, an alkyl or aryl sulfone, an alkyl or aryl sulfide, CHO, or a sulfinate salt. The sulfides may be further oxidized with a reagent, such as potassium peroxymonosulfate, or m-chlorobenzoic acid, to provide sulfoxides or sulfones. The sulfinate salts may be further transformed to produce sulfones and sulfonamides as described below.

More specifically, compounds I ( $A^1 = N$ ,  $A^2 = CH$ ) with D = CN may be obtained by treating a solution of the corresponding halide, preferably iodide I ( $A^1 = N$ ,  $A^2 = CH$ , D = C-I), in a solvent such as THF with an alkyl magnesium reagent, such as cyclopentyl magnesium bromide, at about -78 to 0  $^{O}$ C, preferably about -30 to -40  $^{O}$ C, under an inert atmosphere, for about 1 to 5 h to generate an organomagnesium species I ( $A^1 = N$ ,  $A^2 = CH$ , D = C-Mg). Tosyl cyanide is then added and the reaction allowed to gradually warm to ambient temperature and to proceed for about 1 to 24 h. Following workup and purification, I ( $A^1 = N$ ,  $A^2 = CH$ , D = C-CN) is obtained.

Compounds I ( $A^1 = N$ ,  $A^2 = CH$ ,  $D = C-SO_2R$  where R = alkyl or aryl) may be obtained by treating the organomagnesium species I ( $A^1 = N$ ,  $A^2 = CH$ , D = C-Mg) as generated above with an alkyl or aryl sulfonyl chloride. Alternatively, one may add an alkyl- or aryldisulfide, or an alkyl- or arylthiosulfonate (prepared by oxidizing the corresponding alkyl or aryl disulfide, for example with m- chloroperoxybenzoic acid in a suitable solvent such as methylene chloride) and then heating the reaction at about the reflux temperature of the solvent for about 1 to 3 h to obtain I ( $A^1 = N$ ,  $A^2 = CH$ , D = C-SR, where R = alkyl or aryl) after workup and purification. The resulting product may be oxidized to the corresponding sulfoxide or sulfone with a suitable oxidizing agent such as potassium peroxymonosulfate or m-chloroperoxybenzoic acid.

Compounds I ( $A^1 = N$ ,  $A^2 = CH$ ) with  $D = C-CO_2R$ , where R is an alkyl or an aryl group, may be obtained by treating the organomagnesium species as generated above with an appropriate alkyl or aryl chloroformate, in a solvent such as THF, at about -20 to -78  $^{\circ}$ C, preferably about -40  $^{\circ}$ C, under an inert atmosphere for about 15 min to 1 h before allowing the reaction to warm to room temperature over about 30 min to 1 h. Following quenching, for example with aqueous sodium bicarbonate, workup and purification, I ( $A^1 = N$ ,  $A^2 = CH$ ,  $D = C-CO_2R$ ) is obtained.

Compounds I (A<sup>1</sup> = N, A<sup>2</sup> = CH) with D = C-CHO may be obtained by treating a solution of the corresponding halide, preferably iodide (I: A<sup>1</sup> = N, A<sup>2</sup> = CH, D = C-I), in a solvent such as THF with an alkyl lithium, such as *n*-BuLi at about -50 to -120 °C, preferably about -100 °C, under an inert atmosphere for about 15 min to 1 h. N,N-Dimethylformamide is added and the reaction gradually allowed to warm to about 0 °C and stirred for about 1 h. Following quenching, for example with aqueous ammonium chloride, workup and purification, I (A<sup>1</sup> = N, A<sup>2</sup> = CH, D = C-CHO) is obtained.

One may also synthesize certain compounds of the invention by treating the organomagnesium intermediate as generated above with sulfur dioxide to generate an intermediate magnesium sulfinate salt. This intermediate may be treated with alkylating reagents, such as alkyl halides to produce additional compounds of the formula I ( $A^1 = N$ ,  $A^2 = CH$ ) with  $D = C-SO_2R$  (R = alkyl). The intermediate magnesium sulfinate salt may also be treated with *N*-chlorosuccinimide to generate the sulfonyl chloride I ( $A^1 = N$ ,  $A^2 = CH$ ,  $D = C-SO_2Cl$ ). The sulfonyl chloride can in turn be treated with amines to produce desired sulfonamides I ( $A^1 = N$ ,  $A^2 = CH$ ,  $D = C-SO_2NRR$ ' where R and R'= a hydrogen atom, an alkyl or aryl group, or together comprise part of a heterocyclic ring).

Analogs of I ( $A^1 = N$ ,  $A^2 = CH$ ) with  $D = C-SO_2NRR$ , where R and R together comprise part of a heterocyclic ring and where R and/or R contains a second nitrogen, for example piperazine, can be further substituted on the second nitrogen, for example with acyl, alkyl, aryl, carbarnyl or sulfonyl as described below and outlined in Scheme IV.

In Scheme IV, R" is a functional group transferable by an electrophilic reagent and can be, but is not restricted to, an alkyl group, COR, CONRR', CO<sub>2</sub>R, or SO<sub>2</sub>R, where R or R' is alkyl or aryl.

The compound bearing the heteroatom can be treated with reagents such as an alkanoyl or aroyl chloride, alkanoyl or aroyl anhydride, alkyl halide, alkyl or aryl sulfonyl chlorideor alkyl or aryl isocyanate to produce compounds where I (A<sup>1</sup> = N, A<sup>2</sup> = CH) and D is a carbon substituted with a sulfonamide which itself is further substituted with various groups such as alkyl or aryl amides, alkyl amines, alkyl or aryl sulfonamides, and alkyl or aryl ureas.

More specifically, compounds I ( $A^1 = N$ ,  $A^2 = CH$ ) and where D is a carbon substituted with a piperazine sulfonamide which itself is further N-acylated may be obtained by treating a solution of the corresponding piperazine sulfonamide, in a solvent such as N,N-dimethylformamide with an appropriate carboxylic acid, in the presence of a coupling agent, such as polystyrene resin-bound carbodiimide, at about 20  $^{\circ}$ C for about 2 to 24 h.

Following workup and purification, compounds I ( $A^1 = N$ ,  $A^2 = CH$ ) and where D = is a carbon substituted with an acylated piperazine sulfonamide are obtained.

Alternatively, these compounds may be obtained by treating a solution of the corresponding piperazinesulfonamide, in a solvent such as dichloromethane with an appropriate alkanoyl or aroyl chloride, in the presence of a base, such as triethylamine, at about -20 to 20 °C, preferably about 0 °C for about 15 min to 2 h. Following quenching, for example with aqueous sodium bicarbonate, workup and purification, the desired acylated piperazinesulfonamides are obtained.

Compounds I ( $A^1 = N$ ,  $A^2 = CH$ ) and where D is a carbon substituted with a piperazinesulfonamide which itself participates additionally in an urea linkage may be obtained by treating a solution of the corresponding piperazinesulfonamide in a solvent such as dichloromethane with an appropriate isocyanate, at about 0 to 40  $^{O}$ C, preferably about 20  $^{O}$ C for about 2 to 24 h. Following workup and purification, compounds I ( $A^1 = N$ ,  $A^2 = CH$ ) and where D = is a carbon substituted with an urea functionalized piperazinesulfonamide are obtained.

Alternatively, compounds I (A<sup>1</sup> = N, A<sup>2</sup> = CH) and where D is a carbon substituted with a piperazinesulfonamide which itself is further N-sulfonylated may be obtained by treating a solution of the corresponding piperazinesulfonamide, in a solvent such as dichloromethane with an appropriate sulfonyl chloride, in the presence of a base, such as triethylamine, at about -20 to 20 °C, preferably about 0 °C for about 15 min to 2 h. Following quenching, for example with aqueous sodium bicarbonate, workup and purification, compounds I (A<sup>1</sup> = N, A<sup>2</sup> = CH) and where D = is a carbon substituted with a sulfonylated

The compound I ( $A^1 = N$ ,  $A^2 = D = C$ -Cl, C-Br or C-I) may be treated in a solvent such as THF with an alkyl magnesium bromide, such as cyclopentyl magnesium bromide, at about -78 to 0  $^{O}$ C, preferably about -30 to -40  $^{O}$ C, under an inert atmosphere, for about 1 to 5 h. An aqueous acid, such as 1N hydrogen chloride or saturated NH<sub>4</sub>Cl solution, is then added. Following workup and purification, I ( $A^1 = N$ ,  $A^2 = C$ -Cl, C-Br or C-I, and D = CH) is obtained.

The halogen substituted compound I ( $A^1 = N$ ,  $A^2 = C-Cl$ , C-Br or C-I, and D = CH) may be transformed to an organometallic intermediate I ( $A^1 = N$ ,  $A^2 = C-M$ , D = CH, where M is an metal atom, such as Li or Mg) by treatment with an organometallic reagent, such as an alkyl or aryl lithium or magnesium reagent. This organometallic intermediate may be reacted with an electrophile, such as an N-chloro-, bromo- or iodo- succinimide, tosyl cyanide, an alkyl halide, an alkyl or aryl sulfonyl chloride, an alkyl or aryl disulfide, an alkyl- or arylthiosulfonate, an alkyl or aryl chloroformate, N,N-dimethylformamide or sulfur dioxide, to produce the analog of I ( $A^1 = N$ , D = CH) where  $A^2$  is a carbon substituted with various groups, such as Cl, Br, I, CN, an alkyl group, an alkyl or aryl sulfone, an alkyl or aryl sulfide, CHO, or a sulfinate salt. The sulfides may be further oxidized with a reagent, such as potassium peroxymonosulfate, or m-chlorobenzoic acid, to sulfoxides or sulfones. The sulfinate salts may also be reacted with an alkylating reagent, such as an alkyl bromide or iodide to produce sulfones. Alternatively, the sulfinate salts may be transformed into the sulfonyl chlorides with a chlorinating reagent, such as NCS. The sulfonyl chlorides may be reacted with an amine to produce sulfonamides I  $(A^1 = N,$  $A^2 = C-SO_2NR^1R^2$ , D = CH).

More specifically, compounds I (A<sup>1</sup> = N, D = CH) with A<sup>2</sup> = C-CN, C-SO<sub>2</sub>R or CO<sub>2</sub>R, where R is alkyl or aryl, C-CHO, C-SO<sub>2</sub>Cl and C-SO<sub>2</sub>NRR' may be prepared from the corresponding halide or organomagnesium species as described above (Scheme III) for D.

Functional group transformations well known in the art may be employed to modify the substituents on A<sup>2</sup> illustrated above to obtain additional compounds of the invention.

Functional group transformations also allow the derivatization of  $R^4$ . In particular, when  $R^4$  is a brominated or iodonated benzyl group, these halogens can often be replaced with aryl groups by techniques known in the art, for example by treating a solution of the halogenated benzyl group, with an organometallic reagent such as an aryl boronate, boronic acid or stannane, in a solvent such as a mixture of toluene and ethanol, in the presence of a base, such as aqueous sodium carbonate, with a metal catalyst, such as  $Pd(PPh_3)_4$ , at about 75 to 110  $^{\rm O}$ C, preferably about 85  $^{\rm O}$ C for about 2 to 24 h. Following workup and purification, I ( $R^4 = CH_2C_4H_6Ar$ ) is obtained, where Ar can be, but is not limited to, furyl, phenyl, pyridyl, pyrimidyl and thiophenyl.

Compounds of formula I with  $A^1 = A^2 = D = N$  may be prepared as illustrated in Scheme VI and described below.

Intermediate VII is treated with an alkylating agent such as diethyl sulfate, in a suitable solvent such as aqueous base and THF. After workup and purification, the intermediate is

treated with a suitable oxidizing agent such as potassium peroxymonosulfate to give sulfoxide X. A solution of X is then treated with NaN<sub>3</sub> at ambient temperature for about 12-24 h. Upon workup and purification, carboxylic acid XI is obtained. Intermediate XI is then reacted under standard peptide coupling conditions, for example treatment with 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDC) and 1-hydroxybenzotriazole (HOBT) and a base, such as diisopropylethylamine, in a suitable solvent such as DMF for about 5 to 24 h at ambient temperature. Following workup and purification, I ( $A^1 = A^2 = D = N$ ) is obtained.

Intermediate X (Scheme VI) is treated with formic hydrazide in a suitable solvent such as DMSO, under an inert atmosphere at about 50 to  $100^{\circ}$ C for about 5 to 24 h to provide XII after workup and purification. Intermediate XII is treated with a catalytic amount of an acid, such as p-toluenesulfonic acid in a suitable solvent, such as toluene. Molecular sieves or a trap to collect water formed in the reaction may be employed. The reaction is heated at reflux temperature for about 3 to 12 h. The desired compound of formula I (A<sup>1</sup> = N, A<sup>2</sup> = N, and D = CH) is obtained following purification.

Analogs of I ( $A^1 = N$ ,  $A^2 = N$ ) where D = C substituted with various groups may be prepared as described above for analogs of I ( $A^1 = N$ ,  $A^2 = CH$ ).

The invention is further described by the following synthetic examples.

Thiophosgene (0.723 mL, 9.48 mmol) was added to a solution of 2.75 g (7.90 mmol) XXV in 28 mL CH<sub>2</sub>Cl<sub>2</sub> at 0° C, resulting in an orange solution. Triethylamine (4.40 mL, 31.6 mmol) was added and the dark solution was allowed to warm to room temperature and was stirred overnight. The reaction was diluted with EtOAc, washed with saturated aqueous NH<sub>4</sub>Cl, re-extracted 2X EtOAc, then was dried and concentrated under reduced pressure. The residue was purified via flash chromatography to afford 1.35 g recovered impure XXV as well as 1.08 g impure XXVI. The recovered XXV was subjected to reaction conditions similar to that above, and after isolation and purification yielded an additional 0.28 g of impure XXVI. The two samples were combined and purified again via flash chromatography, to afford 0.92 g of pure compound XXVI. The product was characterized by <sup>1</sup>H NMR and mass spectroscopy.

Triphenylphosphine (1.18 g, 4.51 mmol) was added portionwise to a solution of 580 mg (4.51 mmol) of XXVII in 10 mL of xylenes and was stirred for 2 h at room temperature. A solution of 880 mg (2.25 mmol) of XXVI in 2 mL of xylenes was added and the reaction was heated to reflux for 3 days and then was concentrated under reduced pressure. The residue was purified via flash chromatography to afford 420 mg of impure XXVI, and 290 mg of impure XXVIII contaminated with triphenylphosphine oxide. The sample of XXVIII was treated with 0.49 mL (6.3 mmol) trifluoroacetic acid in 4 mL of 1,2-dichloroethane in a pressure tube, purged with Ar, and heated at 110° C overnight. The reaction was then treated with saturated aqueous Na<sub>2</sub>CO<sub>3</sub>, extracted with ether, then dried and concentrated under reduced pressure. The 420 mg of impure XXVI was treated under conditions similar to that described above. After isolation, both residues were combined and were purified via flash chromatography to afford 120 mg (13%) of XXI as an oil. The product was characterized by <sup>1</sup>H NMR and mass spectroscopy.

### Description of Biological Properties

The biological properties of representative compounds of the formula I were investigated by way of the experimental protocol described below.

# Assay to Determine Inhibition of LFA-1 Binding to ICAM-1

#### Purpose of Assay:

This assay protocol is designed to study the direct antagonism, by a test compound, of the interaction of the CAM, ICAM-1 with the Leukointegrin CD18/CD11a (LFA-1).

#### Description of Assay Protocol:

LFA-1 is immunopurified using the TS2/4 antibody from a 20 g pellet of human JY or SKW3 cells, utilizing a protocol previously described (Dustin, M. J.; et al., J. Immunol. 1992, 148, 2654-2660). The LFA-1 is purified from SKW3 lysates by immunoaffinity chromatography on TS2/4 LFA-1 mAb Sepharose and eluted at pH 11.5 in the presence of 2 mM MgCl<sub>2</sub> and 1% octylglucoside. After collection and neutralization of fractions from the TS2/4 column, samples are pooled and precleared with Protein G agarose.

20

25

30

15

A soluble form of ICAM-1 is constructed, expressed, purified and characterized as previously described (Marlin, S.; et al., Nature, 1990, 344, 70-72 and see Arruda, A.; et al., Antimicrob. Agents Chemother. 1992, 36, 1186-1192). Briefly, isoleucine 454 which is located at the putative boundary between domain 5 of the ectodomain and the transmembrane domain, is changed to a stop codon using standard oligonucleotide-directed mutagenesis. This construction yields a molecule identical with the first 453 amino acids of membrane bound ICAM-1. An expression vector is created with a hamster dihydrofolate reductase gene, a neomycin-resistance marker, and the coding region of the sICAM-1 construct described above, along with the promoter, splice signals, and polyadenylation signal of the SV40 early region. The recombinant plasmid is transfected into CHO DUX cells using standard calcium phosphate methods. Cells are passaged in

selective media (G418) and colonies secreting sICAM-1 are amplified using methotrexate. sICAM-1 is purified from serum-free media using traditional non-affinity chromatographic techniques, including ion exchange and size exclusion chromatography.

LFA-1 binding to ICAM-1 is monitored by first incubating sICAM-1 at 40 µg/mL in 5 Dulbecco's phosphate buffered saline with calcium and magnesium, additional 2 mM MgCl<sub>2</sub> and 0.1 mM PMSF (Diluting Buffer) in a 96-well plate for 30 min at room temperature. Plates are then blocked by the addition of 2% (w/v) bovine serum albumin in Diluting Buffer for 37 °C for 1 h. Blocking solution is removed from wells, and test 10 compounds are diluted and then added followed by the addition of approximately 25 ng of immunoaffinity purified LFA-1. The LFA-1 is incubated in the presence of test compound and ICAM-1 at 37 °C for 1 h. Wells are washed 3 times with Diluting Buffer. The bound LFA-1 is detected by the addition of a polyclonal antibody directed against a peptide corresponding to the CD18 cytoplasmic tail in a 1:100 dilution with Diluting Buffer and 15 1% BSA and allowed to incubate for 45 min at 37 °C. Wells are washed 3 times with Diluting Buffer and the bound polyclonal antibody is detected by the addition of a 1:4000 dilution of horse radish peroxidase conjugated to goat immunoglobulin directed against rabbit immunoglobulin. This reagent is allowed to incubate for 20 min at 37 °C, wells are washed as above and the substrate for the horse radish peroxidase is added to each well to 20 develop a quantitative colorimetric signal proportional to the amount of LFA-1 bound to sICAM-1. Soluble ICAM-1 (60 µg/mL) is used as a positive control for inhibition of the LFA-1/ICAM-1 interaction. The lack of the addition of LFA-1 to the binding assay is used as a background control for all samples. A dose-response curve is obtained for all test compounds.

25

All compounds made in the above examples were tested in this assay and each found to have a  $K_d < 10 \ \mu M$ .

### Description of Therapeutic Use

30

The novel small molecules of formula I provided by the invention inhibit the ICAM-1/LFA-1 dependent homotypic aggregation of human lymphocytes and human lymphocyte adherence to ICAM-1. These compounds have therapeutic utility in the modulation of immune cell activation/proliferation, e.g., as competitive inhibitors of intercellular 5 ligand/receptor binding reactions involving CAMs and Leukointegrins. To be more specific, the compounds of the invention may be used to treat certain inflammatory conditions, including conditions resulting from a response of the non-specific immune system in a mammal (e.g., adult respiratory distress syndrome, shock, oxygen toxicity, multiple organ injury syndrome secondary to septicemia, multiple organ injury syndrome 10 secondary to trauma, reperfusion injury of tissue due to cardiopulmonary bypass, myocardial infarction or use with thrombolysis agents, acute glomerulonephritis, vasculitis, reactive arthritis, dermatosis with acute inflammatory components, stroke, thermal injury, hemodialysis, leukapheresis, ulcerative colitis, necrotizing enterocolitis and granulocyte transfusion associated syndrome) and conditions resulting from a response of the specific 15 immune system in a mammal (e.g., psoriasis, organ/tissue transplant rejection, graft vs. host reactions and autoimmune diseases including Raynaud's syndrome, autoimmune thyroiditis, dermatitis, multiple sclerosis, rheumatoid arthritis, insulin-dependent diabetes mellitus, uveitis, inflammatory bowel disease including Crohn's disease and ulcerative colitis, and systemic lupus erythematosus). The compounds of the invention may also be 20 used in treating asthma or as an adjunct to minimize toxicity with cytokine therapy in the treatment of cancers. In general these compounds may be employed in the treatment of those diseases currently treatable through steroid therapy.

Thus, another aspect of the invention is the provision of a method for the treatment or prophylaxis of the above-described conditions through the administration of therapeutic or prophylactic amounts of one or more compounds of the formula I.

In accordance with the method provided by the invention, the novel compounds of formula I may be administered for either a prophylactic or therapeutic purpose either alone or with other immunosuppressive or antiinflammatory agents. When provided prophylactically,

the immunosuppressive compound(s) are provided in advance of any inflammatory response or symptom (for example, prior to, at, or shortly after the time of an organ or tissue transplant but in advance of any symptoms of organ rejection). The prophylactic administration of a compound of the formula I serves to prevent or attenuate any subsequent inflammatory response (such as, for example, rejection of a transplanted organ or tissue, etc.). The therapeutic administration of a compound of the formula I serves to attenuate any actual inflammation (such as, for example, the rejection of a transplanted organ or tissue). Thus, in accordance with the invention, a compound of the formula I can be administered either prior to the onset of inflammation (so as to suppress an anticipated inflammation) or after the initiation of inflammation.

10

15

20

25

The novel compounds of the formula I may, in accordance with the invention, be administered in single or divided doses by the oral, parenteral or topical routes. A suitable oral dosage for a compound of formula I would be in the range of about 0.1 mg to 10 g per day. In parenteral formulations, a suitable dosage unit may contain from 0.1 to 250 mg of said compounds, whereas for topical administration, formulations containing 0.01 to 1% active ingredient are preferred. It should be understood, however, that the dosage administration from patient to patient will vary and the dosage for any particular patient will depend upon the clinician's judgement, who will use as criteria for fixing a proper dosage the size and condition of the patient as well as the patient's response to the drug.

When the compounds of the present invention are to be administered by the oral route, they may be administered as medicaments in the form of pharmaceutical preparations which contain them in association with a compatible pharmaceutical carrier material. Such carrier material can be an inert organic or inorganic carrier material suitable for oral administration. Examples of such carrier materials are water, gelatin, talc, starch, magnesium stearate, gum arabic, vegetable oils, polyalkylene-glycols, petroleum jelly and the like.

The pharmaceutical preparations can be prepared in a conventional manner and finished dosage forms can be solid dosage forms, for example, tablets, dragees, capsules, and the

like, or liquid dosage forms, for example solutions, suspensions, emulsions and the like. The pharmaceutical preparations may be subjected to conventional pharmaceutical operations such as sterilization. Further, the pharmaceutical preparations may contain conventional adjuvants such as preservatives, stabilizers, emulsifiers, flavor-improvers, wetting agents, buffers, salts for varying the osmotic pressure and the like. Solid carrier material which can be used include, for example, starch, lactose, mannitol, methyl cellulose, microcrystalline cellulose, talc, silica, dibasic calcium phosphate, and high molecular weight polymers (such as polyethylene glycol).

For parenteral use, a compound of formula I can be administered in an aqueous or nonaqueous solution, suspension or emulsion in a pharmaceutically acceptable oil or a mixture
of liquids, which may contain bacteriostatic agents, antioxidants, preservatives, buffers or
other solutes to render the solution isotonic with the blood, thickening agents, suspending
agents or other pharmaceutically acceptable additives. Additives of this type include, for
example, tartrate, citrate and acetate buffers, ethanol, propylene glycol, polyethylene
glycol, complex formers (such as EDTA), antioxidants (such as sodium bisulfite, sodium
metabisulfite, and ascorbic acid), high molecular weight polymers (such as liquid
polyethylene oxides) for viscosity regulation and polyethylene derivatives of sorbitol
anhydrides. Preservatives may also be added if necessary, such as benzoic acid, methyl or
propyl paraben, benzalkonium chloride and other quaternary ammonium compounds.

The compounds of this invention may also be administered as solutions for nasal application and may contain in addition to the compounds of this invention suitable buffers, tonicity adjusters, microbial preservatives, antioxidants and viscosity-increasing agents in an aqueous vehicle. Examples of agents used to increase viscosity are polyvinyl alcohol, cellulose derivatives, polyvinylpyrrolidone, polysorbates or glycerin. Microbial preservatives added may include benzalkonium chloride, thimerosal, chloro-butanol or phenylethyl alcohol.

25

Additionally, the compounds provided by the invention can be administered topically or by suppository.
